

Esports as a field requires accuracy, where one thousandth of a second can determine whether a team or person wins or loses. Different visual and acoustic stimuli need to be correctly responded to efficiently in order to take advantage of the situation and gain the upper hand. 44 (24 casual [CAS]; play >4 hours per week and 20 elite smash [ES]; top 150 globally-ranked competitive Super Smash Bros. Ultimate players as determined by 2024 Lumirank rankings) subjects from local Monterey and CSUMB Esports tournaments voluntarily participated in a Psytool kit test to assess impulse reaction time in milliseconds. Analyses such as a permutation test and a bootstrap confidence interval found no significant group differences for mean impulse reaction time between the ES ($350.68\text{ms} \pm 84.25\text{ms}$) and CAS ($323.89\text{ms} \pm 54.56\text{ms}$) groups ($p=1161$, 95% CI: -72.03ms , 13.91ms). These findings suggest that impulse reaction time is not a distinguishing skill in Super Smash Bros. Ultimate. As Elite SSBU players did not exhibit significantly lower impulse reaction time than casual gamers, this may indicate that gaming performance stems more from specialized training and game-specific skills rather than superior impulse control.
